Technical Report

SAP HANA on NetApp FAS Systems with NFS Configuration Guide

Nils Bauer and Marco Schön, NetApp
March 2020 | TR-4290

Abstract

The NetApp® FAS system product family has been certified for use with SAP HANA in tailored data center integration (TDI) projects. This document describes best practices for a NAS (NFS) storage setup using NetApp ONTAP® with the FAS system product family.

1 Introduction

The NetApp FAS system product family has been certified for use with SAP HANA in tailored data center integration (TDI) projects. The certified enterprise storage system is characterized by the NetApp ONTAP software.

This certification is currently only valid for the following models:

- FAS8020, FAS8040, FAS8060, FAS8080 EX
- FAS2620, FAS2650, FAS2720, FAS2750, FAS8200, FAS8300, FAS8700, FAS9000

A complete list of NetApp’s certified storage solutions for SAP HANA can be found at the Certified and supported SAP HANA hardware directory.

This document describes the ONTAP configuration requirements for the NFS version 3 (NFSv3) or NFS version 4 (NFSv4.0 and NFSv4.1) protocol. For the remainder of this document, NFSv4 refers to both NFSv4.0 and NFSv4.1.

The configuration guides for NetApp FAS systems using FCP and for AFF systems using NFS or FC can be found at the following links:

- SAP HANA on NetApp FAS Systems with Fibre Channel Protocol
- SAP HANA on NetApp AFF Systems with NFS
- SAP HANA on NetApp AFF Systems with Fibre Channel Protocol

Table 1 shows the supported combinations for NFS versions, NFS locking, and the required isolation implementations, depending on the SAP HANA database configuration. NetApp also recommends using NFSv4 for SAP HANA multiple host environments.

Table 1) Supported NFS versions.

This document covers configuration recommendations for SAP HANA running on physical servers and on virtual servers that use VMware vSphere.

For more information about using vSphere with SAP HANA, see the following links:

- Best Practices and Recommendations for Scale-Up Deployments of SAP HANA on VMware vSphere
- Best Practices and Recommendations for Scale-Out Deployments of SAP HANA on VMware vSphere
- TR-4338: SAP HANA on VMware vSphere and NetApp FAS Systems

Note: Always refer to the relevant SAP notes for operating system configuration guidelines and HANA-specific Linux kernel dependencies. For more information, you see SAP note 2235581: SAP HANA Supported Operating Systems.

1.1 SAP HANA Tailored Data Center Integration

NetApp FAS storage controllers are certified in the SAP HANA TDI program using both NFS (NAS) and FC (SAN) protocols. They can be deployed in any of the current SAP HANA scenarios such as SAP Business Suite on HANA, S/4HANA, BW/4HANA, or SAP Business Warehouse on HANA in either single-
host or multiple-host configurations. Any server that is certified for use with SAP HANA can be combined with NetApp certified storage solutions. See Figure 1 for an architecture overview.

Figure 1) SAP HANA TDI.

For more information regarding the prerequisites and recommendations for productive SAP HANA systems, see the following SAP resources:
- SAP HANA Tailored Data Center Integration Frequently Asked Questions
- SAP HANA Storage Requirements

2 Architecture

SAP HANA hosts are connected to storage controllers by using a redundant 10GbE or faster network infrastructure. Data communication between SAP HANA hosts and storage controllers is based on the NFS protocol. A redundant switching infrastructure is recommended in order to provide fault-tolerant SAP HANA host-to-storage connectivity in case of switch or network interface card (NIC) failure. The switches might aggregate individual port performance with port channels in order to appear as a single logical entity at the host level.

Different models of the FAS system product family can be mixed and matched at the storage layer to allow for growth and differing performance and capacity needs. The maximum number of SAP HANA hosts that can be attached to the storage system is defined by the SAP HANA performance requirements and the model of NetApp controller used. The number of required disk shelves is only determined by the capacity and performance requirements of the SAP HANA systems. Figure 2 shows an example configuration with eight SAP HANA hosts attached to a storage high availability (HA) pair.
The architecture can be scaled in two dimensions:

- By attaching additional SAP HANA hosts and/or storage capacity to the existing storage, if the storage controllers provide enough performance to meet the current SAP key performance indicators (KPIs)
- By adding more storage systems with additional storage capacity for the additional SAP HANA hosts

Figure 3 shows an example configuration in which more SAP HANA hosts are attached to the storage controllers. In this example, more disk shelves are necessary to fulfill both the capacity and performance requirements of 16 SAP HANA hosts. Depending on the total throughput requirements, additional 10GbE (or faster) connections to the storage controllers must be added.

Independent of the deployed FAS system, the SAP HANA landscape can also be scaled by adding any of the certified storage controllers to meet the desired node density (Figure 4).
2.1 SAP HANA Backup

The ONTAP software present on all NetApp storage controllers provides a built-in mechanism to back up SAP HANA databases while in operation with no effect on performance. Storage-based NetApp Snapshot™ backups are a fully supported and integrated backup solution available for SAP HANA single containers and for SAP HANA metadata controller (MDC) systems with a single tenant or multiple tenants.

Storage-based Snapshot backups are implemented by using the NetApp SnapCenter® plug-in for SAP HANA. This allows users to create consistent storage-based Snapshot backups by using the interfaces provided natively by SAP HANA databases. SnapCenter registers each of the Snapshot backups into the SAP HANA backup catalog. Therefore, the backups taken by SnapCenter are visible within SAP HANA Studio where they can be selected directly for restore and recovery operations.

NetApp SnapMirror® technology allows enables Snapshot copies that were created on one storage system to be replicated to a secondary backup storage system that is controlled by SnapCenter. Different backup retention policies can then be defined for each of the backup sets on the primary storage and for the backup sets on the secondary storage systems. The SnapCenter Plug-in for SAP HANA automatically manages the retention of Snapshot copy-based data backups and log backups, including the housekeeping of the backup catalog. The SnapCenter Plug-in for SAP HANA also allows the execution of a block integrity check of the SAP HANA database by executing a file-based backup.

The database logs can be backed up directly to the secondary storage by using an NFS mount, as shown in Figure 5) Backup architecture.
Storage-based Snapshot backups provide significant advantages compared to conventional file-based backups. These advantages include, but are not limited to, the following:

- Faster backup (a few minutes)
- Reduced recovery time objective (RTO) due to a much faster restore time on the storage layer (a few minutes) as well as more frequent backups
- No performance degradation of the SAP HANA database host, network, or storage during backup and recovery operations
- Space-efficient and bandwidth-efficient replication to secondary storage based on block changes

For detailed information about the SAP HANA backup and recovery solution using SnapCenter, see TR-4614: SAP HANA Backup and Recovery with SnapCenter.

### 2.2 SAP HANA Disaster Recovery

SAP HANA disaster recovery can be performed either on the database layer by using SAP HANA system replication or on the storage layer by using storage replication technologies. The following section provides an overview of disaster recovery solutions based on storage replication.

For detailed information about the SAP HANA disaster recovery solutions, see TR-4646: SAP HANA Disaster Recovery with Asynchronous Storage Replication.

#### Storage Replication Based on SnapMirror

The same SnapCenter plug-in that is described in section 2.1, “SAP HANA Backup,” is used to provide the asynchronous mirroring solution between a primary and secondary controller. A consistent Snapshot image of the database at the primary site is asynchronously replicated to the disaster recovery site by using NetApp SnapMirror technology. The servers at the disaster recovery site could be used for
development and testing during normal operations to further reduce your TCO, as shown in Figure 6.

Asynchronous storage replication.

Space-efficient, instantaneous NetApp FlexClone® copies can be used at the disaster recovery site to run disaster failover tests without interrupting the replication process. FlexClone copies can also be used to quickly create an SAP full system copy to refresh the test or training systems with current production data.

Figure 6) Asynchronous storage replication.

SnapMirror also offers synchronous replication, which can operate in StrictSync mode. If the write to the secondary storage is not completed for any reason, the application I/O fails, thereby ensuring that the primary and secondary data is identical. Application I/O to the primary resumes only after the SnapMirror relationship returns to the InSync status. If the primary storage fails, application I/O can be resumed on the secondary storage, after failover, with no loss of data. In StrictSync mode, the recovery point objective (RPO) is always zero and the RTO is very low.

Synchronous SnapMirror does not replicate application-consistent Snapshot copies. Therefore, the replication target cannot be used for application or disaster recovery testing, as shown with the asynchronous version of SnapMirror.

Storage Replication Based on MetroCluster

Figure 7 shows a high-level overview of the solution. The storage cluster at each site provides local high availability and is used for the production workload. The data of each site is synchronously replicated to the other location and is available if there is disaster failover.
3 Storage Sizing

The following section provides an overview of the required performance and capacity considerations needed for sizing a storage system for SAP HANA.

Note: Contact NetApp or your NetApp partner sales representative to assist you in creating a properly sized storage environment.

3.1 Performance Considerations

SAP has defined a static set of storage KPIs. These KPIs are valid for all production SAP HANA environments independent of the memory size of the database hosts and the applications that use the SAP HANA database. These KPIs are valid for single-host, multiple-host, Business Suite on HANA, Business Warehouse on HANA, S/4HANA, and BW/4HANA environments. Therefore, the current performance sizing approach depends on only the number of active SAP HANA hosts that are attached to the storage system.

Note: Storage performance KPIs are only mandated for production SAP HANA systems, but you can implement them in all HANA systems.

SAP provides a performance test tool called the Hardware Configuration Check Tool (HWCCT) that is used to validate storage system performance for the active SAP HANA hosts that you have attached. NetApp has tested and predefined the maximum number of SAP HANA hosts that can be attached to a specific storage model, while still fulfilling the required storage KPIs from SAP for production-based SAP HANA systems.

Note: The storage controllers of the certified FAS product family can also be used for SAP HANA with other disk types or disk back-end solutions. However, they must be supported by NetApp and
This document describes disk sizing for SAS HDDs and solid-state drives (SSDs).

**HDDs**

A minimum of 10 data disks (10k RPM SAS) per SAP HANA node is required to fulfill the storage performance KPIs from SAP.

**Note:** This calculation is independent of the storage controller and disk shelf used as well as the capacity requirements of the database.

**Solid-State Drives**

With SSDs, the number of data disks is determined by the SAS connection throughput from the storage controllers to the SSD shelf.

The maximum number of SAP HANA hosts that can be run on a single disk shelf and the minimum number of SSDs required per SAP HANA host were determined by running the SAP performance test tool. This test does not consider the actual storage capacity requirements of the hosts. In addition, you must also calculate the capacity requirements to determine the actual storage configuration needed.

- The 12Gb SAS disk shelf (DS224C) with 24 SSDs supports up to 14 SAP HANA hosts when the disk shelf is connected with 12Gb.
- The 6Gb SAS disk shelf (DS2246) with 24 SSDs supports up to 4 SAP HANA hosts.

The SSDs and the SAP HANA hosts must be equally distributed between both storage controllers.

Table 2 summarizes the supported number of SAP HANA hosts per disk shelf.

<table>
<thead>
<tr>
<th>Maximum number of SAP HANA hosts per disk shelf</th>
<th>6Gb SAS Shelves (DS2246) Fully Loaded with 24 SSDs</th>
<th>12Gb SAS Shelves (DS224C) Fully Loaded with 24 SSDs</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>14</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** This calculation is independent of the storage controller used.

### 3.2 Mixed Workloads

SAP HANA and other application workloads running on the same storage controller or in the same storage aggregate are supported. However, it is a NetApp best practice to separate SAP HANA workloads from all other application workloads.

You might decide to deploy SAP HANA workloads and other application workloads on either the same storage controller or the same aggregate. If so, you must make sure that adequate performance is available for SAP HANA within the mixed workload environment. NetApp also recommends that you use quality of service (QoS) parameters to regulate the effect these other applications could have and to guarantee throughput for SAP HANA applications.

The SAP HWCCT test tool must be used to check if additional SAP HANA hosts can be run on an existing storage controller that is already in use for other workloads. SAP application servers can be safely placed on the same storage controller and/or aggregate as the SAP HANA databases.
3.3 Capacity Considerations

A detailed description of the capacity requirements for SAP HANA is in the SAP HANA Storage Requirements white paper.

Note: The capacity sizing of the overall SAP landscape with multiple SAP HANA systems must be determined by using SAP HANA storage sizing tools from NetApp. Contact NetApp or your NetApp partner sales representative to validate the storage sizing process for a properly sized storage environment.

3.4 HWCCT Configuration for SAP HANA

Starting with SAP HANA 1.0 SPS10, SAP introduced parameters to adjust the I/O behavior and optimize the database for the file and storage system used. These parameters must also be set when storage performance is being tested with the SAP HWCCT tool.

NetApp conducted performance tests to define the optimal values. Table 3 lists the parameters that must be set within the configuration file of SAP HWCCT.

Table 3) HWCCT configuration file parameter values.

</tbody>
</table>

More information about the configuration of SAP HWVAL is in SAP note 1943937.

3.5 Storage Sizing Process Overview

The number of disks per HANA host and the SAP HANA host density for each storage model were determined with HWCCT.

The sizing process requires details such as the number of production and nonproduction SAP HANA hosts, the RAM size of each host, and the backup retention of the storage-based Snapshot copies. The number of SAP HANA hosts determines the storage controller and the number of disks required.

The size of the RAM, net data size on the disk of each SAP HANA host, and the Snapshot copy backup retention period are used as inputs during capacity sizing.

Figure 8 summarizes the sizing process.

Figure 8) Storage sizing overview.
4 Infrastructure Setup and Configuration

The following sections provide SAP HANA infrastructure setup and configuration guidelines.

4.1 Network Setup

Use the following guidelines when configuring the network:

- A dedicated storage network must be used to connect the SAP HANA hosts to the storage controllers with a 10GbE or faster network.
- Use the same connection speed for storage controllers and SAP HANA hosts. If this is not possible, ensure that the network components between the storage controllers and the SAP HANA hosts are able to handle different speeds. For example, you must provide enough buffer space to allow speed negotiation at the NFS level between storage and hosts. Network components are usually switches, but other components within blade chassis, such as the back plane, must be considered as well.
- Disable flow control on all physical ports used for storage traffic on the storage network switch and host layer.
- Each SAP HANA host must have a redundant network connection with a minimum of 10Gb of bandwidth.
- Jumbo frames with a maximum transmission unit (MTU) size of 9,000 must be enabled on all network components between the SAP HANA hosts and the storage controllers.
- In a VMware setup, dedicated VMXNET3 network adapters must be assigned to each running virtual machine.

Figure 9 shows an example with four SAP HANA hosts attached to a storage controller HA pair using a 10GbE network. Each SAP HANA host has an active-passive connection to the redundant fabric.

At the storage layer, four active connections are configured to provide 10Gb throughput for each SAP HANA host. In addition, one spare interface is configured on each storage controller.

At the storage layer, a broadcast domain with an MTU size of 9000 is configured, and all required physical interfaces are added to this broadcast domain. This approach automatically assigns these physical interfaces to the same failover group. All logical interfaces (LIFs) that are assigned to these physical interfaces are added to this failover group.
In general, it is also possible to use HA interface groups on the servers (bonds) and the storage systems (for example, Link Aggregation Control Protocol (LACP) and ifgroups). With HA interface groups, verify that the load is equally distributed between all interfaces within the group. The load distribution depends on the functionality of the network switch infrastructure.

4.2 Time Synchronization
You must synchronize the time between the storage controllers and the SAP HANA database hosts. To do so, set the same time server for all storage controllers and all SAP HANA hosts.

4.3 Storage Controller Setup
This section describes the configuration of the NetApp storage system. You must complete the primary installation and setup according to the corresponding ONTAP setup and configuration guides.

Storage Efficiency
Inline deduplication, cross-volume inline deduplication, inline compression, and inline compaction are supported with SAP HANA in an SSD configuration.
Enabling storage efficiency features in an HDD-based configuration is not supported.

NetApp Volume Encryption
The use of NetApp Volume Encryption (NVE) is supported with SAP HANA.

Quality of Service
QoS can be used to limit the storage throughput for specific SAP HANA systems or other applications on a shared-use controller. One use case would be to limit the throughput of development and test systems so that they cannot influence production systems in a mixed setup.
During the sizing process, you should determine the performance requirements of a nonproduction system. Development and test systems can be sized with lower performance values, typically in the range of 20% to 50% of a production-system KPI as defined by SAP.

Starting with ONTAP 9, QoS is configured on the storage volume level and uses maximum values for throughput (MBps) and the amount of I/O (IOPS).

Large write I/O has the biggest performance effect on the storage system. Therefore, the QoS throughput limit should be set to a percentage of the corresponding write SAP HANA storage performance KPI values in the data and log volumes.

Storage Configuration

The following overview summarizes the required storage configuration steps. Each step is covered in detail in the subsequent sections. In this section, we assume that the storage hardware is set up and that the ONTAP software is already installed. Also, the connections between the storage ports (10GbE or faster) and the network must already be in place.

1. Check the correct SAS stack configuration as described in "Disk Shelf Connection."
2. Create and configure the required aggregates as described in "Aggregate Configuration."
3. Create a storage virtual machine (SVM) as described in "Storage Virtual Machine Configuration."
4. Create LIFs as described in "Logical Interface Configuration."
5. Create volumes within the aggregates as described in "Volume Configuration for SAP HANA Single-Host Systems" and "Volume Configuration for SAP HANA Multiple-Host Systems."
6. Set the required volume options as described in "Volume Options."
7. Set the required options for NFSv3 as described in "NFS Configuration for NFSv3" or for NFSv4 as described in "NFS Configuration for NFSv4."
8. Mount the volumes to namespace and set export policies as described in "Mount Volumes to Namespace and Set Export Policies."

Disk Shelf Connection

With HDDs, a maximum of two DS2246 disk shelves or four DS224C disk shelves can be connected to one SAS stack to provide the required performance for the SAP HANA hosts, as shown in Figure 10. The disks within each shelf must be distributed equally to both controllers of the HA pair.

![Image of Disk shelf connection with HDDs]
With SSDs, a maximum of one disk shelf can be connected to one SAS stack to provide the required performance for the SAP HANA hosts, as shown in Figure 11. The disks within each shelf must be distributed equally to both controllers of the HA pair. With the DS224C disk shelf, quad-path SAS cabling can also be used, but is not required.

Figure 11) Disk shelf connection with SSDs.

Aggregate Configuration

In general, you must configure two aggregates per controller, independent of the disk shelf or drive technology (SSD or HDD) that is used. For FAS2000 series systems, one data aggregate is enough.

Aggregate Configuration with HDDs

Figure 12 shows a configuration for eight SAP HANA hosts. Four SAP HANA hosts are attached to each storage controller. Two separate aggregates, one at each storage controller, are configured. Each aggregate is configured with $4 \times 10 = 40$ data disks (HDDs).

Figure 12) Aggregate layout with HDDs.

Aggregate Configuration with SSDs

Figure 13 shows a configuration of eight SAP HANA hosts using a DS224C disk shelf connected with 12Gb SAS. Four SAP HANA hosts are attached to each storage controller. Two separate aggregates, one at each storage controller, are configured. Each aggregate is configured with six data disks (SSDs).
Storage Virtual Machine Configuration

Multiple SAP landscapes with SAP HANA databases can use a single SVM. An SVM can also be assigned to each SAP landscape, if necessary, in case they are managed by different teams within a company.

Logical Interface Configuration

For SAP HANA production systems, you must use different LIFs for mounting the data volume and the log volume from the SAP HANA host. Therefore at least two LIFs are required per storage controller.

The data and log volume mounts of different SAP HANA hosts can share a physical storage network port by using either the same LIFs or by using individual LIFs for each mount.

The maximum number of data and log volume mounts per physical interface are shown in Table 4.

Table 4) Maximum number of mounts per physical interface.

<table>
<thead>
<tr>
<th>Ethernet Port Speed</th>
<th>10GbE</th>
<th>25GbE</th>
<th>40GbE</th>
<th>100GeE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of log or data volume mounts per physical port</td>
<td>2</td>
<td>6</td>
<td>12</td>
<td>24</td>
</tr>
</tbody>
</table>

Note: Sharing one LIF between different SAP HANA hosts might require a remount of data or log volumes to a different LIF. This change avoids performance penalties if a volume is moved to a different storage controller.

Development and test systems can use more data and volume mounts or LIFs on a physical network interface.

For production, development, and test systems, the /hana/shared file system can use the same LIF as the data or log volume.

Volume Configuration for SAP HANA Single-Host Systems

Figure 14 shows the volume configuration of four single-host SAP HANA systems. The data and log volumes of each SAP HANA system are distributed to different storage controllers. For example, volume SID1_data_mnt00001 is configured on controller A, and volume SID1_log_mnt00001 is configured on controller B.
Note: If only one storage controller of an HA pair is used for the SAP HANA systems, data and log volumes can also be stored on the same storage controller.

Note: If the data and log volumes are stored on the same controller, access from the server to the storage must be performed with two different LIFs: one LIF to access the data volume and one to access the log volume.

Figure 14) Volume layout for SAP HANA multiple single-host systems.

For each SAP HANA DB host, a data volume, a log volume, and a volume for /hana/shared are configured. Table 5 shows an example configuration for single-host SAP HANA systems.

Table 5) Volume configuration for SAP HANA single-host systems.

<table>
<thead>
<tr>
<th>Purpose</th>

**Volume Configuration for SAP HANA Multiple-Host Systems**

Figure 15 shows the volume configuration of a 4+1 SAP HANA system. The data and log volumes of each SAP HANA host are distributed to different storage controllers. For example, volume SID1_data1_mnt00001 is configured on controller A, and volume SID1_log1_mnt00001 is configured on controller B.

**Note:** If only one storage controller of an HA pair is used for the SAP HANA system, the data and log volumes can also be stored on the same storage controller.

**Note:** If the data and log volumes are stored on the same controller, access from the server to the storage must be performed with two different LIFs: one to access the data volume and one to access the log volume.

Figure 15) Volume layout for SAP HANA multiple-host systems.

For each SAP HANA host, a data volume and a log volume are created. The /hana/shared volume is used by all hosts of the SAP HANA system. Table 7 shows an example configuration for a multiple-host SAP HANA system with four active hosts.
Table 7) Volume configuration for SAP HANA multiple-host systems.

<table>
<thead>
<tr>

<td>/usr/sap/SID</td>
<td>Mounted at host 5</td>
</tr>
</tbody>
</table>

Volume Options

You must verify and set the volume options listed in Table 9 on all SVMs. For some of the commands, you must switch to the advanced privilege mode within ONTAP.

Table 9) Volume options.

<table>
<thead>
<tr>
<th>Action</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disable visibility of Snapshot directory</td>
<td>vol modify -vserver &lt;vserver-name&gt; -volume &lt;volname&gt; -snapdir-access false</td>
</tr>
</tbody>
</table>
### Action | Command
--- | ---
Disable automatic Snapshot copies | `vol modify -vserver <vserver-name> -volume <volname> -snapshot-policy none`
Disable access time update except of the SID_shared volume | `set advanced
vol modify -vserver <vserver-name> -volume <volname> -atime-update false
set admin`

#### NFS Configuration for NFSv3

The NFS options listed in Table 10 must be verified and set on all storage controllers. For some of the commands shown in Table 10, you must switch to the advanced privilege mode within ONTAP.

**Table 10) NFSv3 options.**

<table>
<thead>
<tr>
<th>Action</th>
<th>Command</th>
</tr>
</thead>
</table>
| Enable NFSv3 | `nfs modify -vserver <vserver-name> v3.0 enabled`
| ONTAP 9:
Set NFS TCP maximum transfer size to 1MB | `set advanced
nfs modify -vserver <vserver_name> -tcp-max-xfer-size 1048576
set admin`
| ONTAP 8:
Set NFS read and write size to 64KB | `set advanced
nfs modify -vserver <vserver-name> -v3-tcp-max-read-size 65536
nfs modify -vserver <vserver-name> -v3-tcp-max-write-size 65536
set admin`

#### NFS Configuration for NFSv4

The NFS options listed in Table 11 must be verified and set on all SVMs.

For some of the commands in Table 11, you must switch to the advanced privilege mode within ONTAP.

**Table 11) NFSv4 options.**

<table>
<thead>
<tr>
<th>Action</th>
<th>Command</th>
</tr>
</thead>
</table>
| Enable NFSv4 | `nfs modify -vserver <vserver-name> -v4.1 enabled`
| ONTAP 9:
Set NFS TCP maximum transfer size to 1MB | `set advanced
nfs modify -vserver <vserver_name> -tcp-max-xfer-size 1048576
set admin`
| ONTAP 8:
Set NFS read and write size to 64KB | `set advanced
nfs modify -vserver <vserver-name> -tcp-max-xfer-size 65536
set admin`
| Disable NFSv4 access control lists (ACLs) | `nfs modify -vserver <vserver_name> -v4.1-acl disabled`
### Action | Command
--- | ---
Set NFSv4 domain ID | `nfs modify -vserver <vserver_name> -v4-id-domain <domain-name>`
Disable NFSv4 read delegation | `nfs modify -vserver <vserver_name> -v4.1-read-delegation disabled`
Disable NFSv4 write delegation | `nfs modify -vserver <vserver_name> -v4.1-write-delegation disabled`
Set the NFSv4 lease time | `set advanced nfs modify -vserver <vserver_name> -v4-lease-seconds 10 set admin`
Disable NFSv4 numeric ids | `nfs modify -vserver <vserver_name> -v4-numeric-ids disabled`

**Note:** For NFS version 4.0, replace 4.1 with 4.0 in the previous commands.

**Note:** The NFSv4 domain ID must be set to the same value on all Linux servers (/etc/idmapd.conf) and SVMs, as described in “SAP HANA Installation Preparations for NFSv4.”

**Note:** If you are using NFSV4.1, pNFS is enabled and used by default (recommended).

### Mount Volumes to Namespace and Set Export Policies
When a volume is created, the volume must be mounted to the namespace. In this document, we assume that the junction path name is the same as the volume name. By default, the volume is exported with the default policy. The export policy can be adapted if necessary.

### 4.4 Host Setup
All the steps described in this section are valid for both SAP HANA environments on physical servers and for SAP HANA running on VMware vSphere.

### Configuration Parameter for SUSE Linux Enterprise Server
Additional kernel and configuration parameters at each SAP HANA host must be adjusted for the workload generated by SAP HANA.

**SUSE Linux Enterprise Server 12 and 15**
Starting with SUSE Linux Enterprise Server 12 SP1, the kernel parameter must be set in a configuration file in the `/etc/sysctl.d` directory. For example, a configuration file with the name 91-NetApp-HANA.conf must be created.

```plaintext
net.core.rmem_max = 16777216
net.core.wmem_max = 16777216
net.core.rmem_default = 16777216
net.core.wmem_default = 16777216
net.core.optmem_max = 16777216
net.ipv4.tcp_rmem = 65536 16777216 16777216
net.ipv4.tcp_wmem = 65536 16777216 16777216
net.core.netdev_max_backlog = 300000
net.ipv4.tcp_slow_start_after_idle=0
net.ipv4.tcp_no_metrics_save = 1
net.ipv4.tcp_moderate_rcvbuf = 1
net.ipv4.tcp_window_scaling = 1
net.ipv4.tcp_timestamps = 1
net.ipv4.tcp_sack = 1
```
If NFSv3 is used for connecting the storage, the `sunrpc.tcp_max_slot_table_entries` parameter must be set in `/etc/modprobe.d/sunrpc.conf`. If the file does not exist, it must first be created by adding the following line:

```
options sunrpc tcp_max_slot_table_entries=128
```

### Configuration Parameter for Red Hat Enterprise Linux 7.2 or Later

You must adjust additional kernel and configuration parameters at each SAP HANA host if the workload generated by SAP HANA.

If NFSv3 is used for connecting the storage, you must set the parameter `sunrpc.tcp_max_slot_table_entries` in `/etc/modprobe.d/sunrpc.conf`. If the file does not exist, you must first create it by adding the following line:

```
options sunrpc tcp_max_slot_table_entries=128
```

Starting with Red Hat Enterprise Linux 7.2, you must set the kernel parameters in a configuration file in the `/etc/sysctl.d` directory. For example, a configuration file with the name `91-NetApp-HANA.conf` must be created.

```
net.core.rmem_max = 16777216
net.core.wmem_max = 16777216
net.core.rmem_default = 16777216
net.core.wmem_default = 16777216
net.core.optmem_max = 16777216
net.ipv4.tcp_rmem = 65536 16777216 16777216
net.ipv4.tcp_wmem = 65536 16777216 16777216
net.core.netdev_max_backlog = 300000
net.ipv4.tcp_slow_start_after_idle=0
net.ipv4.tcp_no_metrics_save = 1
net.ipv4.tcp_window_scaling = 1
net.ipv4.tcp_timestamps = 1
net.ipv4.tcp_sack = 1
```

### Create Subdirectories in `/hana/shared` Volume

**Note**: The examples show an SAP HANA database with SID=NF2.

To create the required subdirectories, take one of the following actions:

- For a single-host system, mount the `/hana/shared` volume and create the `shared` and `usr-sap` subdirectories.

```
shlrx300s8-50:/mnt # mount <storage-hostname>:/NF2_shared /mnt/tmp
shlrx300s8-50:/mnt # cd /mnt/tmp
shlrx300s8-50:/mnt/tmp # mkdir shared
shlrx300s8-50:/mnt/tmp # mkdir usr-sap
shlrx300s8-50:/mnt/tmp # umount /mnt/tmp
```

- For a multiple-host system, mount the `/hana/shared` volume and create the `shared` and the `usr-sap` subdirectories for each host.

The example commands show a 2+1 multiple-host HANA system.

```
shlrx300s8-50:/mnt # mount <storage-hostname>:/NF2_shared /mnt/tmp
shlrx300s8-50:/mnt # cd /mnt/tmp
shlrx300s8-50:/mnt/tmp # mkdir shared
shlrx300s8-50:/mnt/tmp # mkdir usr-sap-host1
shlrx300s8-50:/mnt/tmp # mkdir usr-sap-host2
shlrx300s8-50:/mnt/tmp # mkdir usr-sap-host3
shlrx300s8-50:/mnt/tmp # cd ..
shlrx300s8-50:/mnt/tmp # umount /mnt/tmp
```
Create Mount Points

Note: The examples show an SAP HANA database with SID=NF2.

To create the required mount point directories, take one of the following actions:

- For a single-host system, create mount points and set the permissions on the database host.

```
stlrx300s8-50:/  # mkdir -p /hana/data/NF2/mnt00001
stlrx300s8-50:/  # mkdir -p /hana/log/NF2/mnt00001
stlrx300s8-50:/  # mkdir -p /hana/shared
stlrx300s8-50:/  # mkdir -p /usr/sap/NF2

stlrx300s8-50:/  # chmod -R 777 /hana/log/NF2
stlrx300s8-50:/  # chmod -R 777 /hana/data/NF2
stlrx300s8-50:/  # chmod -R 777 /hana/shared
stlrx300s8-50:/  # chmod -R 777 /usr/sap/NF2
```

- For a multiple-host system, create mount points and set the permissions on all worker and standby hosts.

The following example commands are for a 2+1 multiple-host HANA system.

- First worker host:

```
stlrx300s8-50:~  # mkdir -p /hana/data/NF2/mnt00001
stlrx300s8-50:~  # mkdir -p /hana/data/NF2/mnt00002
stlrx300s8-50:~  # mkdir -p /hana/log/NF2/mnt00001
stlrx300s8-50:~  # mkdir -p /hana/log/NF2/mnt00002
stlrx300s8-50:~  # mkdir -p /hana/shared
stlrx300s8-50:~  # mkdir -p /usr/sap/NF2

stlrx300s8-50:~  # chmod -R 777 /hana/log/NF2
stlrx300s8-50:~  # chmod -R 777 /hana/data/NF2
stlrx300s8-50:~  # chmod -R 777 /hana/shared
stlrx300s8-50:~  # chmod -R 777 /usr/sap/NF2
```

- Second worker host:

```
stlrx300s8-51:~  # mkdir -p /hana/data/NF2/mnt00001
stlrx300s8-51:~  # mkdir -p /hana/data/NF2/mnt00002
stlrx300s8-51:~  # mkdir -p /hana/log/NF2/mnt00001
stlrx300s8-51:~  # mkdir -p /hana/log/NF2/mnt00002
stlrx300s8-51:~  # mkdir -p /hana/shared
stlrx300s8-51:~  # mkdir -p /usr/sap/NF2

stlrx300s8-51:~  # chmod -R 777 /hana/log/NF2
stlrx300s8-51:~  # chmod -R 777 /hana/data/NF2
stlrx300s8-51:~  # chmod -R 777 /hana/shared
stlrx300s8-51:~  # chmod -R 777 /usr/sap/NF2
```

- Standby host:

```
stlrx300s8-52:~  # mkdir -p /hana/data/NF2/mnt00001
stlrx300s8-52:~  # mkdir -p /hana/data/NF2/mnt00002
stlrx300s8-52:~  # mkdir -p /hana/log/NF2/mnt00001
stlrx300s8-52:~  # mkdir -p /hana/log/NF2/mnt00002
stlrx300s8-52:~  # mkdir -p /hana/shared
stlrx300s8-52:~  # mkdir -p /usr/sap/NF2

stlrx300s8-52:~  # chmod -R 777 /hana/log/NF2
stlrx300s8-52:~  # chmod -R 777 /hana/data/NF2
stlrx300s8-52:~  # chmod -R 777 /hana/shared
stlrx300s8-52:~  # chmod -R 777 /usr/sap/NF2
```

Mount File Systems

Different mount options must be used depending on the NFS version and ONTAP release. The following file systems must be mounted to the hosts:

- /hana/data/SID/mnt0000*
- /hana/log/SID/mnt0000*
- /hana/shared
- /usr/sap/SID

Table 12 shows the NFS versions that must be used for the different file systems for single-host and multiple-host SAP HANA databases.

**Table 12) NFS versions to be used.**

<table>
<thead>
<tr>
<th>File systems</th>
<th>SAP HANA single host</th>
<th>SAP HANA multiple hosts</th>
</tr>
</thead>
<tbody>
<tr>
<td>/hana/data/SID/mnt0000*</td>
<td>NFSv3 or NFSv4</td>
<td>NFSv4</td>
</tr>
<tr>
<td>/hana/log/SID/mnt0000*</td>
<td>NFSv3 or NFSv4</td>
<td>NFSv4</td>
</tr>
<tr>
<td>/hana/shared</td>
<td>NFSv3 or NFSv4</td>
<td>NFSv3 or NFSv4</td>
</tr>
<tr>
<td>/usr/sap/SID</td>
<td>NFSv3 or NFSv4</td>
<td>NFSv3 or NFSv4</td>
</tr>
</tbody>
</table>

Table 13 shows the mount options for the various NFS versions and ONTAP releases. The common parameters are independent of the NFS and ONTAP versions.

For NFSv3, you must switch off NFS locking to avoid NFS lock cleanup operations if there is a software or server failure.

With ONTAP 9, the NFS transfer size can be configured up to 1MB. Specifically, with 40GbE or faster connections to the storage system, you must set the transfer size to 1MB to achieve the expected throughput values.

**Table 13) Mount options.**

<table>
<thead>
<tr>
<th>Common Parameter</th>
<th>NFSv3</th>
<th>NFSv4</th>
<th>NFSv4.1</th>
<th>NFS Transfer Size with ONTAP 9</th>
<th>NFS Transfer Size with ONTAP 8</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw, bg, hard, timeo=600, noatime, noconnect=n</td>
<td>vers=3, nolock,</td>
<td>vers=4, minorversion=0, lock</td>
<td>vers=4, minorversion=1, lock</td>
<td>rsiz=1048576, wsize=1048576,</td>
<td>rsiz=65536, wsize=65536,</td>
</tr>
</tbody>
</table>

**Note:** To improve read performance with NFSv3, it is recommended that you use the `nconnect=n` mount option, which is available with SUSE Linux Enterprise Server 12 SP4 or later.

**Note:** Performance tests show that `nconnect=8` provides good results.

**Note:** Do not use the option `nconnect` for NFSv4.x.

To mount the file systems during system boot with the `/etc/fstab` configuration file, complete the following steps:

The following example shows a single host SAP HANA database with SID=NF2 using NFSv3 and an NFS transfer size of 1MB.

1. Add the required file systems to the `/etc/fstab` configuration file.

```
# cat /etc/fstab
<storage-vif-data01>:/NF2_data_mnt00001 /hana/data/NF2/mnt00001 nfs rw,vers=3,hard,timeo=600,rsiz=1048576,wsiz=1048576,bg,nowtime,nolock 0 0
<storage-vif-log01>:/NF2_log_mnt00001 /hana/log/NF2/mnt00001 nfs rw,vers=3,hard,timeo=600,rsiz=1048576,wsiz=1048576,bg,nowtime,nolock 0 0
<storage-vif-data01>:/NF2_shared/usr-sap /usr/sap/NF2 nfs rw,vers=3,hard,timeo=600,rsiz=1048576,wsiz=1048576,bg,nowtime,nolock 0 0
<storage-vif-data01>:/NF2_shared/shared /hana/shared nfs rw,vers=3,hard,timeo=600,rsiz=1048576,wsiz=1048576,bg,nowtime,nolock 0 0
```
2. Run `mount -a` to mount the file systems on all hosts.

The next example shows a multiple-host SAP HANA database with SID=NF2 using NFSv4.1 for data and log file systems and NFSv3 for the `/hana/shared` and `/usr/sap/NF2` file systems. An NFS transfer size of 1MB is used.

1. Add the required file systems to the `/etc/fstab` configuration file on all hosts.

   **Note:** The `/usr/sap/NF2` file system is different for each database host. The following example shows `/NF2_shared/usr_sap_host1`.

   ```
   stlrx300s8-5:/ # cat /etc/fstab
   <storage-vif-data01>:/NF2_data_mnt00001 /hana/data/NF2/mnt00001 nfs rw, vers=4
   minorversion=1,hard,timeo=600,rsize=1048576,waize=1048576,bg,noatime,lock 0 0
   <storage-vif-data02>:/NF2_data_mnt00002 /hana/data/NF2/mnt00002 nfs rw, vers=4
   minorversion=1,hard,timeo=600,rsize=1048576,waize=1048576,bg,noatime,lock 0 0
   <storage-vif-log01>:/NF2_log_mnt00001 /hana/log/NF2/mnt00001 nfs rw, vers=4
   minorversion=1,hard,timeo=600,rsize=1048576,waize=1048576,bg,noatime,lock 0 0
   <storage-vif-log02>:/NF2_log_mnt00002 /hana/log/NF2/mnt00002 nfs rw, vers=4
   minorversion=1,hard,timeo=600,rsize=1048576,waize=1048576,bg,noatime,lock 0 0
   <storage-vif-data02>:/NF2_shared/usr_sap_host1 /usr/sap/NF2 nfs
   rw,vers=3,hard,timeo=600,rsize=1048576,wsize=1048576,bg,noatime,nolock 0 0
   <storage-vif-data02>:/NF2_shared/shared /hana/shared nfs
   rw,vers=3,hard,timeo=600,rsize=1048576,wsize=1048576,bg,noatime,nolock 0 0
   ```

2. Run `mount -a` to mount the file systems on all hosts.

### 4.5 SAP HANA Installation Preparations for NFSv4

NFS version 4 and higher requires user authentication. This authentication can be accomplished by using a central user management tool such as a Lightweight Directory Access Protocol (LDAP) server or with local user accounts. The following sections describe how to configure local user accounts.

The administration user `<sidadm>` and the `sapsys` group must be created manually on the SAP HANA hosts and the storage controllers before the installation of the SAP HANA software begins.

#### SAP HANA Hosts

If it doesn’t exist, the `sapsys` group must be created on the SAP HANA host. A unique group ID must be chosen that does not conflict with the existing group IDs on the storage controllers.

The user `<sidadm>` is created on the SAP HANA host. A unique ID must be chosen that does not conflict with existing user IDs on the storage controllers.

For a multiple-host SAP HANA system, the user and group ID must be the same on all SAP HANA hosts. The group and user are created on the other SAP HANA hosts by copying the affected lines in `/etc/group` and `/etc/passwd` from the source system to all other SAP HANA hosts.

**Note:** The NFSv4 domain must be set to the same value on all Linux servers (`/etc/idmapd.conf`) and SVMs. Set the domain parameter “Domain = <domain-name>” in the file `/etc/idmapd.conf` for the Linux hosts.

#### Storage Controllers

The user ID and group ID must be the same on the SAP HANA hosts and the storage controllers. The group and user are created by entering the following commands on the storage cluster:

```bash
vserver services unix-group create -vserver <vserver> -name <group name> -id <group id>
vserver services unix-user create -vserver <vserver> -user <user name> -id <user-id> -primary-gid <group id>
```

Additionally, set the group ID of the UNIX user root of the SVM to 0.
4.6 I/O Stack Configuration for SAP HANA

Starting with SAP HANA 1.0 SPS10, SAP introduced parameters to adjust the I/O behavior and optimize the database for the file and storage systems used.

NetApp conducted performance tests to define the ideal values. The following table lists the optimal values inferred from the performance tests.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>max_parallel_io_requests</td>
<td>128</td>
</tr>
<tr>
<td>async_read_submit</td>
<td>on</td>
</tr>
<tr>
<td>async_write_submit_active</td>
<td>on</td>
</tr>
<tr>
<td>async_write_submit_blocks</td>
<td>all</td>
</tr>
</tbody>
</table>

For SAP HANA 1.0 versions up to SPS12, these parameters can be set during the installation of the SAP HANA database, as described in SAP note 2267798: Configuration of the SAP HANA Database During Installation Using hdbparam.

Alternatively, the parameters can be set after the SAP HANA database installation by using the hdbparam framework.

```
nf2adm@stlrx300s8-50:/usr/sap/NF2/HDB00> hdbparam --paramset fileio.max_parallel_io_requests=128
nf2adm@stlrx300s8-50:/usr/sap/NF2/HDB00> hdbparam --paramset fileio.async_write_submit_active=on
nf2adm@stlrx300s8-50:/usr/sap/NF2/HDB00> hdbparam --paramset fileio.async_read_submit=on
nf2adm@stlrx300s8-50:/usr/sap/NF2/HDB00> hdbparam --paramset fileio.async_write_submit_blocks=all
```

Starting with SAP HANA 2.0, hdbparam has been deprecated, and the parameters have been moved to global.ini. The parameters can be set using SQL commands or SAP HANA Studio. For more details, see SAP note 2399079: Elimination of hdbparam in HANA 2.

4.7 SAP HANA Data Volume Size

As the default, SAP HANA uses only one data volume per SAP HANA service. Due to the maximum file size limitation of the file system, we recommend limiting the maximum data volume size.

To do so automatically, set the following parameter in global.ini in the section [persistence]:

```
datavolume_striping = true
datavolume_striping_size_gb = 8000
```

This creates a new data volume after the 8,000GB limit is reached. SAP note 240005 question 15 provides more information.

4.8 SAP HANA Software Installation

Install on Single-Host System

The SAP HANA software installation does not require any additional preparation for a single-host system.

Install on Multiple-Host System

To install SAP HANA on a multiple-host system, complete the following steps:

1. Using the SAP hdbclm installation tool, start the installation by running the following command at one of the worker hosts. Use the addhosts option to add the second worker (stlrx300s8-51) and the standby host (stlrx300s8-52).
**SAP HANA Lifecycle Management - SAP HANA Database 2.00.030.00.1522209842**

</table>
| Version 2.3 | March 2015 | Added new STONITH implementation for SAP HANA SPS9  
Added compute node setup and HANA installation section                                             |
| Version 3.0 | October 2015| Added NFSv4 support for cDOT  
Updated sysctl parameter  
Included I/O parameter for SAP HANA and HWVAL > SPS10                                            |
| Version 3.1 | March 2016 | Updated capacity sizing  
Updated mount options for /hana/shared  
Updated sysctl parameter                                                                    |
| Version 4.0 | February 2017| New NetApp storage systems and disk shelves  
New features of ONTAP 9  
Support for 40GbE  
New OS releases (SUSE Linux Enterprise Server 12 SP1 and Red Hat Enterprise Linux 7.2)  
New SAP HANA release                                                                 |
| Version 4.1 | July 2017  | Minor updates                                                                                                                                           |
| Version 5.0 | September 2018| New NetApp storage systems  
New OS releases (SUSE Linux Enterprise Server 12 SP3 and Red Hat Enterprise Linux 7.4)  
Additional minor changes  
SAP HANA 2.0 SPS3                                                                 |
| Version 5.1 | September 2019| New OS releases (SUSE Linux Enterprise Server 12 SP4, SUSE Linux Enterprise Server 15, and Red Hat Enterprise Linux 7.6)  
Max data volume size  
Minor changes                                                                                           |
| Version 5.2 | December 2019| New NetApp storage systems  
New OS release SUSE Linux Enterprise Server 15 SP1                                                                                           |
| Version 5.3 | March 2020  | Support of nconnect for NFSv3  
New OS release Red Hat Enterprise Linux 8                                                                                                         |
Refer to the **Interoperability Matrix Tool (IMT)** on the NetApp Support site to validate that the exact product and feature versions described in this document are supported for your specific environment. The NetApp IMT defines the product components and versions that can be used to construct configurations that are supported by NetApp. Specific results depend on each customer's installation in accordance with published specifications.
